Abstract

Indonesia is known for its excessive rainfall. Rainfall trends in an area have different characteristics. Differences in latitude, apparent motion of the sun, geographical position, topography, and the interaction of many forms of air circulation all contribute to this. Rainfall time series is essential for engineering planning, particularly for water infrastructure like irrigation, dams, urban drainage, ports, and wharves. Although meteorological technologies provide short-term rainfall predictions, long-term rainfall prediction is difficult and fraught with uncertainty. Unpredictability and seasonality can cause complex behavior in rainfall time series. This research utilizes the Singular Spectrum Analysis approach to extract trends; seasonality, cyclists, and noise can all be identified with potentially high accuracy.

1 Introduction

Medan is the capital and largest city of the Indonesian province of North Sumatra. North Sumatra is a region of the Indonesian Maritime Continent with substantial rainfall variability [1-3]. Medan is highly strategic based on its geographical conditions, as indicated by the coordinates $1^{\circ} - 4^{\circ}$ N and $98^{\circ} - 100^{\circ}$ E. It is placed near the equatorial line, passed by the Bukit Barisan mountains, and flanked by the Malacca Strait and the Indian Ocean in [4]. This allows the rainfall environment to be influenced by global climate phenomena, and regional-scale climatic influences such as monsoons, tropical disturbances, and convergence zones are considered [5,6].

Medan City has recently suffered exceptional rain intensity, and a number of regions in the city are river basins that discharge into the sea. Excessive rainfall can cause flooding on many roadways and in residential areas. Rainfall patterns are classified in [7] as low (0–100 mm), medium (100–300 mm), high (300–500 mm), and extremely high (>500 mm). Excessive rainfall has the potential to generate floods, flash floods, landslides, and strong winds, especially in places prone to hydrometeorological disasters.

Identification is based on prediction results. Estimating the future value of past data requires high sensitivity and the ability to understand the characteristics of the data so that future probabilities can be estimated [8,9]. Singular spectrum analysis is one method for predicting, belonging to the area of non-parametric methods that do not require initial data assumptions [10-12]. It is possible to find and extract trends, seasonality, cyclists, and noise, which are potentially powerful forecasting techniques.

2 Materials and Methods

2.1 Singular spectrum analysis

The basics of SSA have been explained in detail in [13]. The SSA approach has two complementary stages, which are the decomposition and reconstruction stages. The decomposition stage has two essential steps which are embedding and singular value decomposition. Embedding is the process of forming the original series into the path matrix; SVD decomposes the track matrix and divides the data into trend, seasonality, monthly components, and noise based on their single values. Then the reconstruction stage has two critical steps: creating groups, which involves decomposition of the path matrix, and diagonal averages to reconstruct a new time series.

Step 1. Decomposition: The concept of embedding is the path matrix, which transfers the one-dimensional time series of length N, into a sequence of L-dimensional vectors $(i = 1, K = N - L + 1)$. The window length L , $(1 \lt L \lt N)$ is the single parameter in this delay technique. The columns of the (LxK) trajectory matrix will be formed of the K vectors Xi . The trajectory matrix X is a Hankel matrix with equal elements on the diagonals ($i + j = const$).

$$
X = \begin{bmatrix} x_1 & x_2 & x_3 & \cdots & x_K \\ x_2 & x_3 & x_4 & \cdots & x_{K+1} \\ x_L & x_{L+1} & x_{L+2} & \cdots & x_N \end{bmatrix}
$$
 (2.1)

Singular Value Decomposition transforms the trajectory matrix into a sum of rank-one biorthogonal elementary matrices. From the $S = XXT$ matrix, the eigenvalues (λ_k) of S taken in decreasing order of magnitude $(1 \le k \le L)$ and eigenvector (U_k) can be calculated and then sorted by the ortho-normal system of the eigenvectors of the matrix S corresponding to these eigenvalues. Then calculate the i -th element of the k principal components that will be formed $V_i = X^T U_i / \sqrt{\lambda_i}$. Then the SVD of the path matrix can be calculated by $X_i = \sqrt{\lambda_i} U_i V_i^T$. SVD can be represented as

$$
X = X_1 + X_2 + \dots + X_d \tag{2.2}
$$

Step 2. Reconstruction: The concept of grouping in the reconstruction stage involves taking the results of path matrix decomposition and uniting those that are considered similar to form several groups. Then diagonal

averaging is used to reconstruct a new time series by transforming each elementary matrix of the grouped decomposition. The diagonal averaging algorithm transforms Y into the reconstructed time series y_1 , using the formula:

$$
y_k = \begin{cases} \frac{1}{k} \sum_{m=1}^{k} a^*_{m,k-m+1}, 1 \le k < 0\\ \frac{1}{0-1} \sum_{m=1}^{0-1} a^*_{m,k-m+1}, 0 \le k < P+1\\ \frac{1}{N-k+1} \sum_{m=k-P+1}^{N-P+1} a^*_{m,k-m+1}, P+1 \le k < N \end{cases} \tag{2.3}
$$

Another expansion by applying the Hankelization procedure to all matrix components can be written as:

$$
\tilde{Y}^{(k)} = \left(\tilde{y}_1^{(k)}, \dots, \tilde{y}_N^{(k)}\right) \tag{2.4}
$$

2.2 SSA forecasting

In this research using SSA recurrent forecasting. Thus M new data points will be determined to be forecasted, can be written as : $G_{N+M} = (g_1, g_2,$

$$
g_i \begin{cases} \tilde{y}_i, & i = 0, 1, ..., N \\ \sum_{j=1}^{L-1} r_j g_{i-j}, & i = N+1, ..., N+M \end{cases}
$$
 (2.5)

The concept of SSA recurrent forecasting is to create a model

$$
y_{i+d} = \sum_{k=1}^{d} r_k y_{i+d-k}, 1 \le i \le N - d \tag{2.6}
$$

To obtain a model for SSA recurrent forecasting, the LRF coefficient $(r_1, ..., r_d)$ can be estimated from the eigenvector at the SVD. With $P = (p_1, p_2, ..., p_{L-1}, p_L)$ and $P^{\nabla} = (p_1, p_2, ..., p_{L-1})$ using the formula:

$$
(r_{L-1}, \dots, r_1)^T = \frac{1}{1 - v^2} \sum_{i=1}^{L-1} \pi_i P_i^{\nabla}, v^2 = \sum_{i=1}^{L-1} \pi_i^2
$$
\n(2.7)

2.3 Forecasting accuracy

2.3.1 Mean Absolute Percentage Error (MAPE)

Forecasting accuracy using MAPE to measure the accuracy of prediction results with actual data in the form of an average absolute error proportion and MAPE criteria explained in [14].

$$
MAPE = \frac{1}{n} \sum_{t=1}^{n} \frac{|Y_t - \hat{Y}_t|}{Y_t} \times 100\%
$$
\n(2.8)

With MAPE criteria If $\lt 10\%$ = highly accurate forecasting, $10-20\%$ = good forecasting, $20-50\%$ = reasonable forecasting, and $> 50\%$ = weak and inaccurate forecasting.

2.3.2 Tracking Signal

The tracking signal is used to determine the possibility of using the forecasting results if the pattern changes. If the tracking signal value is outside the acceptable limit $(+/- 5)$, then the forecasting model must be reviewed, as explained in [15].

$$
Tracking Signal = \frac{\sum_{1}^{n} e_n}{\sum_{1}^{n} \frac{|e_n|}{n}}
$$
\n
$$
(2.9)
$$

3 Results and Discussion

3.1 Singular spectrum analysis

The data utilized in this research are the rainfall time series of Medan City for the observation period of January 2017–December 2022 from [7]. The plot shows that the data pattern identifies the influence of trend and seasonality over several time.

Fig. 1. Plot of the Rainfall Time Series of Medan City

Step 1. Decomposition: First step in decomposition process is embedding by determining the window length. The data in this case is 60. The optimum L is determined by conducting experiments up to $L = 30$, then choosing the MAPE with the minimum value. It is obtained at a minimum of $L = 13$.

Table 1. Decomposition

With $L = 13$ and $K = 48$, the Hankel matrix can be organized as shown below:

From the Hankel matrix, the SVD step produces 13 eigentriples. Eigentriples consist of singular value (λ_i) , eigenvector (U_i) , and principal component (V_i) .

Table 3. Eigenvector (U_i) from X matrix

N _O		ຳ	\cdots	V_{13}	
	-0.136	0.039	\cdots	-0.044	
	-0.694	0.012	\cdots	0.066	
47	-1.244	0.067	\cdots	0.043	
48	-1.285	0.076	\cdots	-0.016	

Table 4. Principal Component (V_i) from X matrix

Step 2. Reconstruction: The grouping step with a scree plot shows the estimation of the number of groups that will be formed.

Fig. 2. Scree plot

The plot shows that there will probably be around 2 groups formed. To facilitate grouping by calculating the period value of each eigenvector. Adjacent periodicities are indicated to be in the same group. Several possible groups can be formed along with their respective MAPE values, as follows:

Table 5. MAPE values

No	Model	MAPE
	Trend $(1,2,11)$	18.35
	Seasonal (4,6,13,8-10)	
	Trend $(1,2)$	18,58
	Seasonal (4,6,13,8-11)	
	Trend (1)	17.33
	Seasonal (2,4,6,13,8-11)	

The diagonal averaging step in the reconstruction is to create a new series from groups that have been formed as below:

No	Actual	Reconstruction		Diagonal Averaging	Residual	
		Trend	Seasonal			
	312	265.33	8.81	274.14	37.86	
	124	256.62	-137.49	119.13	4.87	
59	494	285.67	134.78	420,45	73.55	
60	174	278.06	5.55	283.61	-109.61	

Table 6. Diagonal averaging step to create a new series

3.2 SSA forecasting

Forecasting model-based SSA recurrent forecasting using the LRF coefficient as follows:

$$
g_i = \sum_{j=1}^{L-1} r_j g_{i-j} = 12{,}1135(g_{i-1}) + (-1{,}0817)(g_{i-2}) + \dots + (-2{,}3728)(g_{i-12})
$$

3.3 Forecasting accuracy

Forecasting accuracy using MAPE and the tracking signal, it is known that the tracking signal values for the 12 forecasted time periods are within acceptable tolerance limits.

N ₀	Outsample	Forecast	Tracking Signal	MAPE	
	D_t	F,			
61	213	379,88	$-1,00$	17,33%	
62	296	382,19	$-1,21$		
63	232	256,50	$-1,27$		
64	169	366,41	$-1,78$		
65	135	217,03	$-1,96$		
66	319	259,62	$-1,69$		
67	150	249,78	$-1,94$		
68	514	177,40	$-0,74$		
69	243	275,75	$-0,83$		
70	376	226,24	$-0,39$		
71	526	257,47	0,32		
72	321	328,28	0,30		

Table 7. Forecasting accuracy

The results of forecasting are as follows:

Table 8. Forecasting the rainfall time series of Medan City for January - December 2023

4 Conclusion

The results of the Medan City rainfall forecast for January–December 2023 show that almost average rainfall is in the high category because it is in the range of 300–500 mm each month. This can be a reference in many matters, such as engineering planning, especially for water infrastructure such as irrigation, dams, and urban drainage. Besides that, this information can be an illustration for local governments in making policies.
